- Future

Introduction

- Calibrations are currently performed at static conditions:
 - Time consuming, i.e. expensive
 - Often a minimum number of measurement points to reduce costs:
Representativeness to actual measurement conditions?
 - Hysteresis is often significant but often not included
 - In many cases RH probes are used at non-static conditions
- Target of this work:
 - Efficient but comprehensive calibration procedure based on measurements at non-static conditions

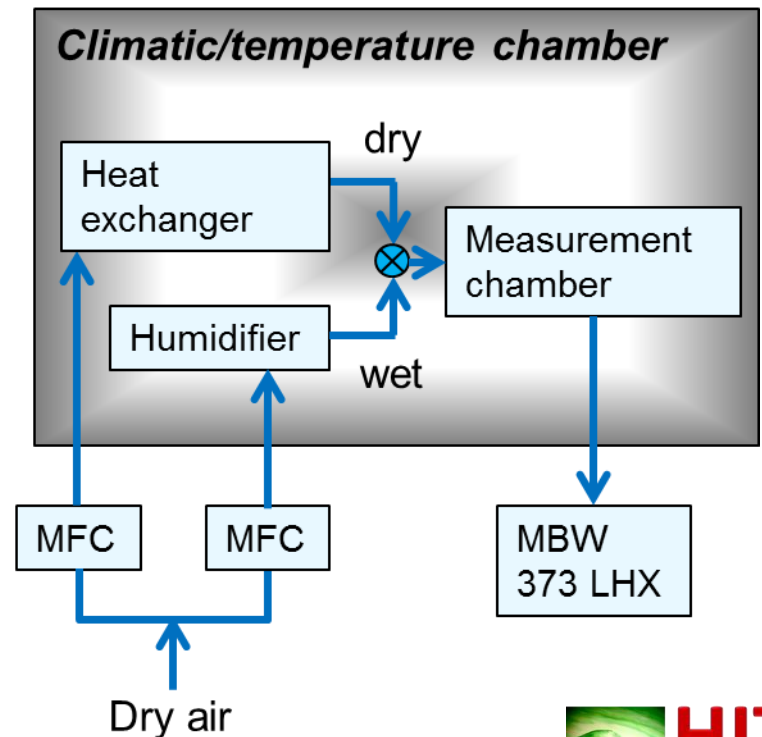

A new modular humidity calibration setup developed at VTT MIKES

- The system can easily be installed any commercial temperature test chamber with inner volume of 200 dm³ or larger
- A LabView program enables automatic calibrations in static and non-static conditions

A new modular humidity calibration setup developed at VTT MIKES

- Humidity is controlled by two mass flow controllers located outside the temperature test chamber
- Quick couplings for easy assembling
- Heater in the humidifier to compensate evaporative cooling

Slow ramp configuration

- Speed is limited by the volume (12 dm³; flow rate 1 dm³/min)

Fast ramp configuration

- Sensors have to be tested separately

Dynamic characteristics of a reference

- Chilled mirror hygrometer:
 - Accurate but suffer from instabilities and limited speed in non-static measurements
- Capacitive sensors:
 - Can be fast but suffer from drift
- Solution:
Combination of a chilled mirror hygrometer and a capacitive reference sensor
 - During calibration measurement the capacitive sensor is checked against the chilled mirror hygrometer at static conditions.

To MBW

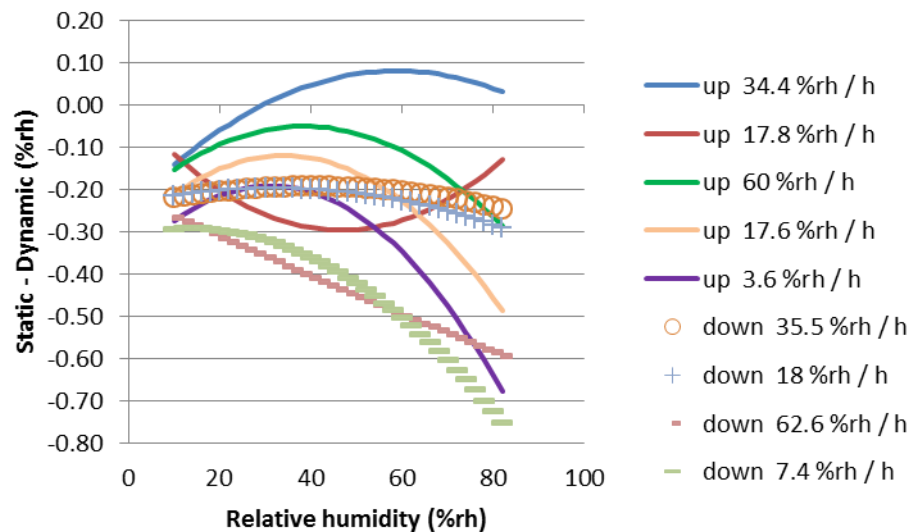

Measurements

- Measurement scheme (different speed rates)

Measurements at +40 °C

Future

- Tests with different humidity sensors will be completed
- Recommendation on a non-static calibration procedure will be prepared
- VTT MIKES is developing a field calibrator operating with non-static (and also static) calibration scheme

Thank you!
